Task 2 – Install Git & Configure Identity

Git & GitHub Fundamentals (Industry Workflow) | Estimated Time: 45 Minutes

Step 1 – Install Git on Ubuntu

Run the following commands in your terminal to update the package list and install Git:

```
sudo apt update
sudo apt install git -y
```

Step 2 – Verify Installation

Confirm that Git was installed successfully:

```
git --version
```

Expected output: git version 2.x.x

Step 3 – Configure Git Identity

Run each command separately. These set the name and email attached to every commit you make. Replace the placeholders with your actual name and email.

```
git config --global user.name "Your Name"
git config --global user.email "your@email.com"
git config --list
```

Understanding Every Configuration Entry

- **user.name** — The name attached to every Git commit you create.
- **user.email** — The email attached to every commit. GitHub uses this to link commits to your account.
- **--global flag** — Applies settings to *all* repositories for your Linux user. Settings are saved in `~/.gitconfig`.

Git has three configuration levels (highest priority wins):

- **system** `(/etc/gitconfig)` — Applies to all users on the machine.
- **global** `(~/.gitconfig)` — Applies to all repos for your user (what you set above).
- **local** `(.git/config)` — Applies only to one specific repository; overrides global.

To see which file each setting comes from, run: `git config --list --show-origin`

Deliverable

Take screenshots of the following and submit them:

- ✓ **Terminal output of `git --version` confirming Git is installed.**
- ✓ **Terminal showing the three `git config` commands running without errors.**
- ✓ **Output of `git config --list` showing user.name and user.email.**
